anongw / blog

Production

Hard to believe, but in this two years I deployed the anonymous gateway in two companies (*thank you PRISM!*). One exactly built as in this (semi) tutorial, the other one ran by a rack server, equipped with a dual quad core Xeon (16 threads, 16GB RAM), clusterized to another box for **high availability**. I was gone really crazy the first weeks adding rules on multiple layers: iptables, privoxy, squid, vpn, clusterized dhcp and dns, etc. The main problem has been to exclude address of web banking for the administration office: https, distributed geographically servers, and paranoid security system are really an headache. I solved installing FoxyProxy in the clients and customizing the rules.

40 privoxy and tor instances over a **40** round robin squid cache proxy peers, **2** TOR TransPort on different instances each user's MacAddress to torify the ports different from *80* tcp.

(One i2p tunnel each **10** privoxy instances)

20 persons behind the anongw.

I have had work (paid) for more then 1 year and... I really enjoyed a lot

dnscrypt

DNSCrypt is a tool for securing communications between a client (our AnonGW) and a DNS resolver. Description

dnscrypt-proxy provides local service which can be used directly as your local resolver or as a DNS forwarder, encrypting and authenticating requests using the DNSCrypt protocol and passing them to an upstream server, by default OpenDNS who run this on their resolvers.

The DNSCrypt protocol uses high-speed high-security elliptic-curve cryptography and is very similar to DNSCurve, but focuses on securing communications between a client and its first-level resolver.

While **NOT** providing end-to-end security or **anonymity**, it protects the local network, which is often the weakest point of the chain, against man-in-the-middle attacks. It also provides some confidentiality to DNS queries. In our POC can be a good compromise between anonymity and full resolution of any type of queries that actually the tor system can't resolve.

Download the current version (in May 2013 the version is **1.3.0**):

```
wget http://download.dnscrypt.org/dnscrypt-proxy/dnscrypt-proxy
```

and **gpg --verify** the signature.

Compile and install it:

```
AnonGW:~$ bunzip2 -cd dnscrypt-proxy-*.tar.bz2 | tar xvf -
AnonGW:~$ cd dnscrypt-proxy-* && ./configure && make -j2
AnonGW:~# make install
```

This is an example of the init script:

```
AnonGW:~# cat /etc/init.d/dnscrypt
```

```
#!/bin/sh
### BEGIN INIT INFO
# Provides:          dnscrypt
# Required-Start:    $network $remote_fs $syslog
# Required-Stop:     $network $remote_fs $syslog
# Default-Start:     2 3 4 5
# Default-Stop:      0 1 6
# Short-Description: Start dnscrypt
# Description:       Encrypt DNS queries.
### END INIT INFO
# TEST http://www.opendns.com/welcome
DAEMON="/usr/local/sbin/dnscrypt-proxy"
NAME="dnscrypt"
dnscrypt_start()
{
    /bin/echo "Starting dnscrypt"
    /sbin/ifconfig lo:2 127.0.0.2 up
    dnscrypt-proxy --user=bind  --local-address=127.0.0.2:40 --
}
dnscrypt_stop()
{
    echo "Stopping dnscrypt"
    start-stop-daemon --oknodo --stop --quiet --retry=0/3/KILL/
    /sbin/ip addr del 127.0.0.2/8 dev lo label lo:2
}
case "$1" in
    start)
   dnscrypt_start
   ;;
  stop)
   dnscrypt_stop
  ;;
  restart|force-reload)
   dnscrypt_stop
  dnscrypt_start
   ;;
    *)
   echo "Usage: /etc/init.d/$NAME {start|stop|restart|force-rel
   exit 1
   ;;
```

```
esac
exit 0
```

Start and check:

```
AnonGW:~# /etc/init.d/dnscrypt start && netstat -nlapo|grep dns
Starting dnscrypt
tcp        0      0 127.0.0.2:40            0.0.0.0:*
udp        0      0 0.0.0.0:58146           0.0.0.0:*
udp        0      0 127.0.0.2:40            0.0.0.0:*
unix  3      [ ]         STREAM     CONNECTED      219530   308
unix  3      [ ]         STREAM     CONNECTED      219529   308
unix  2      [ ]         DGRAM                     219528   308
```

That's all folks.

tor

Below the *n* configuration files for each *n* TOR instance (these are minimal configurations and obviously it's possible to add relay configurations or hidden services).

1th

```
AnonGW:~# cat /etc/tor/torrc
```

```
User debian-tor
SocksPort 9050 # what port to open for local application connections
SocksListenAddress 127.0.0.1 # accept connections only from localhost
VirtualAddrNetwork 10.192.0.0/10
AutomapHostsOnResolve 1
AutomapHostsSuffixes .exit,.onion,.i2p.xyz
DNSPort 127.0.1.1:53
Log notice syslog
RunAsDaemon 1
DataDirectory /var/lib/tor
ControlPort 9051
CookieAuthentication 1
```

2nd

```
AnonGW:~# cat /etc/tor/torrc2
```

```
User debian-tor
ControlSocket /var/run/tor/control2
ControlSocketsGroupWritable 1
CookieAuthentication 1
CookieAuthFileGroupReadable 1
CookieAuthFile /var/run/tor/control2.authcookie
SocksPort 9150 # what port to open for local application connections
```

```
SocksListenAddress 127.0.0.1 # accept connections only from localhost
TransPort $DefaultGW:9443
VirtualAddrNetwork 10.192.0.0/10
AutomapHostsOnResolve 1
AutomapHostsSuffixes .exit,.onion,.i2p.xyz
DNSPort 127.0.0.2:53
Log notice syslog
RunAsDaemon 1
DataDirectory /var/lib/tor2
ControlPort 9151
```

3rd

```
AnonGW:~# cat /etc/tor/torrc3
```

```
User debian-tor
ControlSocket /var/run/tor/control3
ControlSocketsGroupWritable 1
CookieAuthentication 1
CookieAuthFileGroupReadable 1
CookieAuthFile /var/run/tor/control3.authcookie
SocksPort 9250 # what port to open for local application connections
SocksListenAddress 127.0.0.1 # accept connections only from localhost
VirtualAddrNetwork 10.192.0.0/10
AutomapHostsOnResolve 1
AutomapHostsSuffixes .exit,.onion,.i2p.xyz
DNSPort 127.0.0.3:53
TransPort 9040
TransPort $DefaultGW:9040
Log notice syslog
RunAsDaemon 1
DataDirectory /var/lib/tor3

DNSPort 127.0.0.6:53
Log notice syslog
RunAsDaemon 1
DataDirectory /var/lib/tor6
ControlPort 9551
```

7th

```
AnonGW:~# cat /etc/tor/torrc7
```

```
User debian-tor
ControlSocket /var/run/tor/control7
ControlSocketsGroupWritable 1
CookieAuthentication 1
CookieAuthFileGroupReadable 1
CookieAuthFile /var/run/tor/control7.authcookie
SocksPort 9650 # what port to open for local application connections
SocksListenAddress 127.0.0.1 # accept connections only from localhost
VirtualAddrNetwork 10.192.0.0/10
AutomapHostsOnResolve 1
AutomapHostsSuffixes .exit,.onion,.i2p.xyz
DNSPort 127.0.0.7:53
Log notice syslog
RunAsDaemon 1
```

```
DataDirectory /var/lib/tor7
ControlPort 9651
```

8th

```
AnonGW:~# cat /etc/tor/torrc8
```

```
User debian-tor
ControlSocket /var/run/tor/control8
ControlSocketsGroupWritable 1
CookieAuthentication 1
CookieAuthFileGroupReadable 1
CookieAuthFile /var/run/tor/control8.authcookie
SocksPort 9750 # what port to open for local application connections
SocksListenAddress 127.0.0.1 # accept connections only from localhost
VirtualAddrNetwork 10.192.0.0/10
AutomapHostsOnResolve 1
AutomapHostsSuffixes .exit,.onion,.i2p.xyz
DNSPort 127.0.0.8:53
Log notice syslog
RunAsDaemon 1
DataDirectory /var/lib/tor8
ControlPort 9751
```

Note:

To prepare the *N* TOR instances we have to add data directories for each demon and we have to change the TOR related Apparmor configuration file:

```
root@AnonGW:~# mkdir /var/lib/tor{2,3,4,5,6,7,8} && chown debian-tor:debian-tor /var
```

APPARMOR configuration

```
AnonGW:~# cat /etc/apparmor.d/usr.sbin.tor
```

```
/usr/sbin/tor {
  #include <abstractions/base>
  #include <abstractions/nameservice>
  network tcp,
  network udp,
  capability chown,
  capability dac_override,
  capability fowner,
  capability fsetid,
  capability setgid,
  capability setuid,
  /proc/sys/kernel/random/uuid r,
  /sys/devices/system/cpu/ r,
  /sys/devices/system/cpu/** r,
  /etc/tor/* r,
  /usr/share/tor/** r,
  owner /var/lib/tor/** rwk,
  owner /var/lib/tor2/** rwk,
  owner /var/lib/tor3/** rwk,
  owner /var/lib/tor4/** rwk,
```

```
  owner /var/lib/tor5/** rwk,
  owner /var/lib/tor6/** rwk,
  owner /var/lib/tor7/** rwk,
  owner /var/lib/tor8/** rwk,
  owner /var/log/tor/* w,

  /{,var/}run/tor/control8.authcookie.tmp rw,
  # Site-specific additions and overrides. See local/README for details.
  #include <local/usr.sbin.tor>
}
```

Those are simple (horrible) scripts to manage multiple demons: [FIX]

```
AnonGW:~# cat /usr/local/bin/RestartTor
```

```
#!/bin/bash
/usr/sbin/service tor stop ; /bin/sleep 6 ; /usr/sbin/service tor start
```

```
AnonGW:~# cat /etc/init.d/tor
```

```
#! /bin/bash

```

Note:

Before running the demons we have to create log directories:

```
root@AnonGW:~# mkdir /var/log/privoxy/privoxy{2,3,4,5,6,7,8}
```

Those are simple (horrible) scripts to manage multiple demons: **[FIX]**

```
root@AnonGW:~# cat /usr/local/bin/RestartPrivoxy
```

```
#!/bin/bash
/usr/sbin/service privoxy stop ; /bin/sleep 6 ; /usr/sbin/service privoxy start
```

```
root@AnonGW:~# cat /etc/init.d/privoxy
```

```
#! /bin/sh

squid3

The original idea to use multiple balanced instances of TOR was borrowed from this article.

Below is the configuration file **squid.conf**:

```
AnonGW:~# cat /etc/squid3/squid.conf
```

```
visible_hostname DEEP_WEB_PROXY
cache_mgr anonymous
client_db on
detect_broken_pconn on
dns_defnames on
dns_retransmit_interval 2 seconds
dns_timeout 5 minutes
forwarded_for off
half_closed_clients off
httpd_suppress_version_string on
ignore_unknown_nameservers on
pipeline_prefetch on
retry_on_error on
strip_query_terms off
uri_whitespace strip

icp_port 0
icp_access deny all
redirect_rewrites_host_header off
dns_nameservers 127.0.0.1
http_port $DefaultGW:3128 intercept
```

```
forward_timeout 90 seconds
connect_timeout 90 seconds
read_timeout 220 seconds
request_timeout 90 seconds
peer_connect_timeout 90 seconds
persistent_request_timeout 4 minutes
client_lifetime 20 hours

ident_lookup_access deny all

forwarded_for delete
```

Note:

We have to create a new cache directory in the encrypted device:

```
mkdir /var/spool/cache/squid3/ && chown proxy:proxy /var/spool/cache/squid3
```

This configuration may be redundant in some directives when used in chain with Privoxy.

We have to pay attention to the **cache_peer** directives: we need *N* directives for all *N* Privoxy parent proxies (here *N* = 8) and in **/etc/hosts**:

```
127.0.0.1 localhost
127.0.0.1 localhost2
127.0.0.1 localhost3
127.0.0.1 localhost4
127.0.0.1 localhost5
127.0.0.1 localhost6
127.0.0.1 localhost7
127.0.0.1 localhost8
```

where *localhostN* are the names referred to the number of the N clustered parent proxies.

To log in 'tormail': **/etc/squid3/cookie_allow**

```
AnonGW:~# cat /etc/squid3/cookie_allow
.jhiwjjlqpyawmpjx.onion
```

Cron-script to get the list in **/etc/squid3/Malware-domains.txt** and **/etc/squid3/ad_block.txt**:

```
AnonGW:~# cat /usr/local/bin/update-domains.sh
```

```
#!/bin/bash
mkdir /tmp/miep
touch /tmp/malware.tmp
for i in `/usr/bin/python /usr/local/bin/ml.py`; do mkdir -p /tmp/miep/$i; done
ls /tmp/miep/ > /tmp/malware.tmp
diff -a /etc/squid3/Malware-domains.txt /tmp/malware.tmp >> /tmp/diff.tmp
patch /etc/squid3/Malware-domains.txt /tmp/diff.tmp
rm /tmp/malware.tmp /tmp/diff.tmp
rm -rf /tmp/miep
wget -O /etc/squid3/ad_block.txt 'http://pgl.yoyo.org/adservers/serverlist.php?hostf
echo "keke done!"

AnonGW:~# cat /usr/local/bin/ml.py
    import re
import urllib2

# download website
request = urllib2.Request('http://www.malwaredomainlist.com/mdl.php?sort=Domain&asco
opener = urllib2.build_opener()
try:
    content = opener.open(request).read()
except:
    print "FAIL!"
    content = ""

re_tr = re.compile('<tr(.*?)</tr>')
re_td = re.compile('<td>(.*?)</td>')

for tr in re_tr.findall(content):
    try:
        tds = re_td.findall(tr)
        domain = tds[1]
        ip = tds[2]

        to_out = domain
        if domain == '-':
            to_out = ip

        print to_out.replace("<wbr>", "")
    except:
        pass
```

testing environment

The testing environment has this *variables* :

$[FIX] ==> something of horrible to fix urgently - any comment with a suggestion will be appreciated.

N = *n* = number of concurrent Privoxy and TOR processes = "**8**" in this proof of concept.

Networking

```
External NIC = $ExtNIC ==> Bridge on $ExtBr

Internal NIC = $IntNIC ==> Bridge on $IntBr

IP Address External NIC = $ExtBr_IP = $Ext_IP

IP Address Internal NIC = $IntBr_IP = $DefaultGW (Default Gateway)

OpenVPN network = $VPN ==> NIC = $tun

LAN = $IntNet | KVM network = $vir_net | LXC network = $lxc_net

KVM bridged NIC = $virbr | LXC bridged NIC = $lxcbr
```

Note: the network bridge is useful when you isolate processes or systems with LXC or KVM (ex.: eepsites or hidden services).

Storage (simple layout)

```

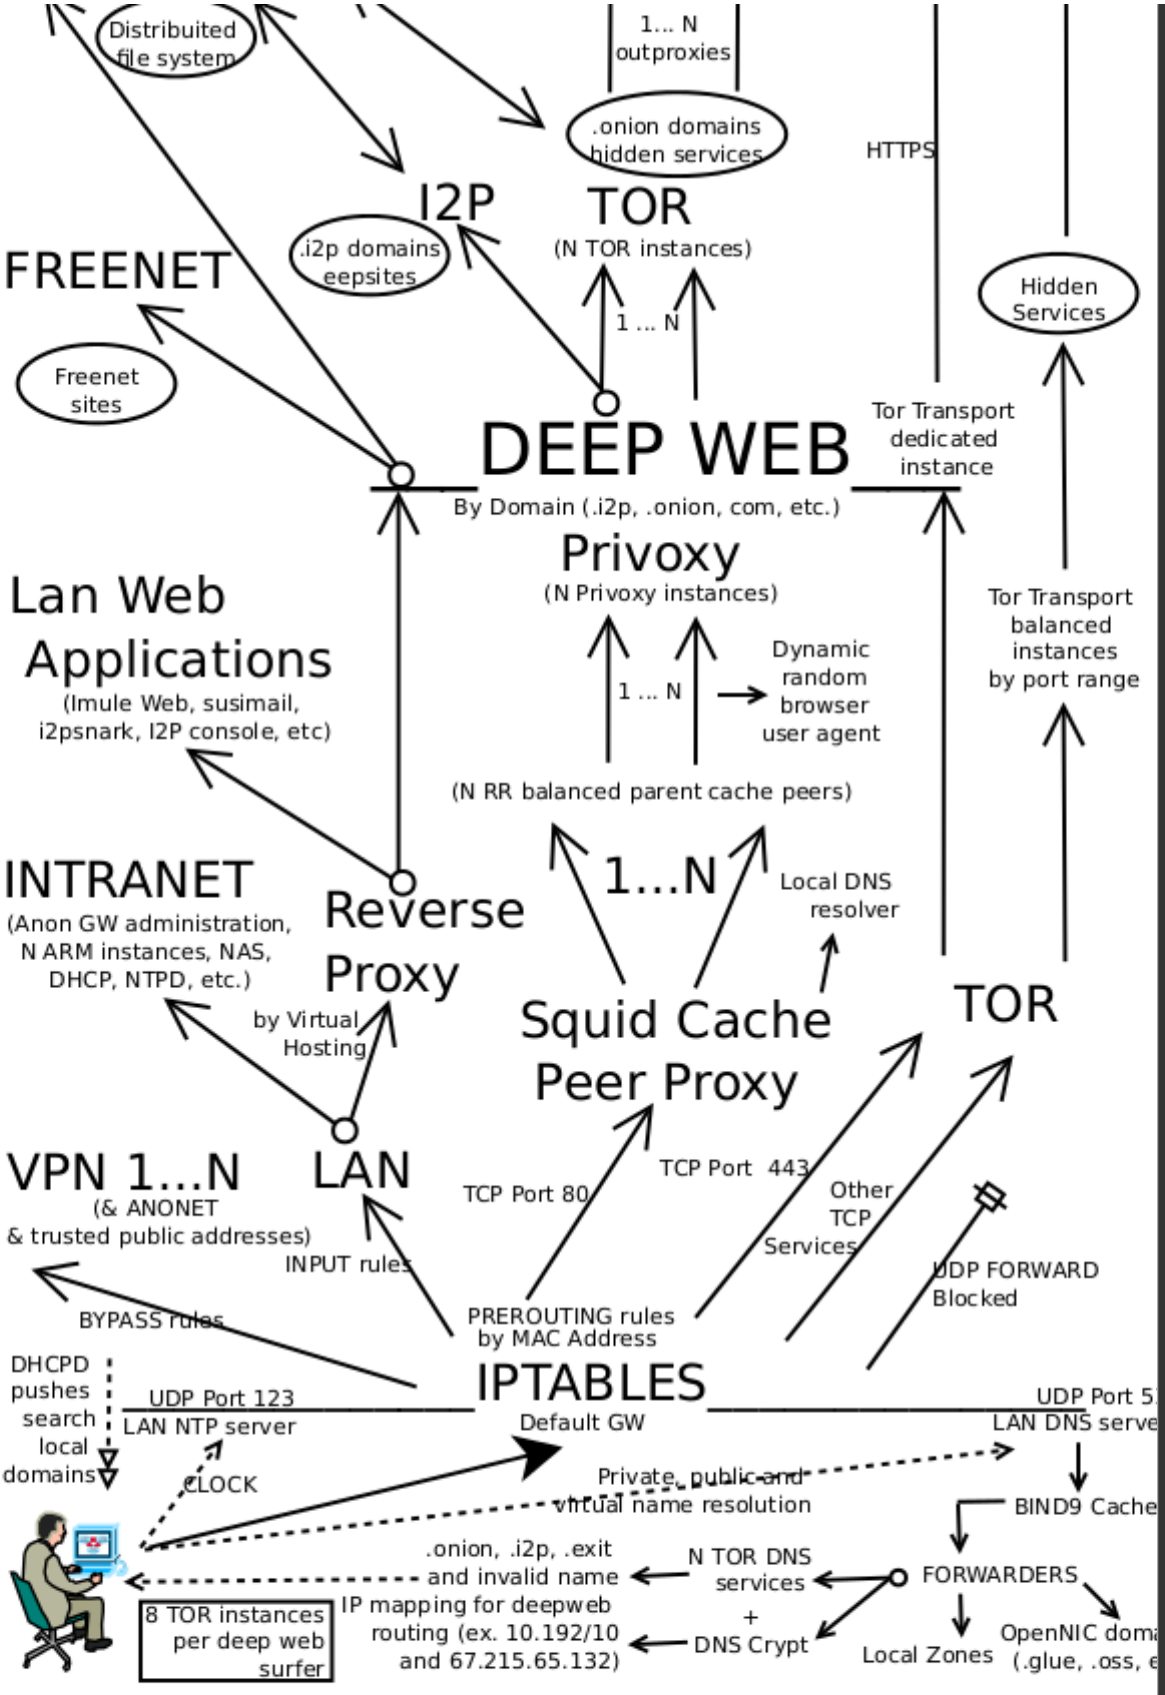
deep web proxy

This is the general scheme:



Distributed file system
1... N outproxies
.onion domains hidden services
HTTPS
I2P
TOR
(N TOR instances)
.i2p domains eepsites
FREENET
1 ... N
Hidden Services
Freenet sites
DEEP WEB
By Domain (.i2p, .onion, com, etc.)
Tor Transport dedicated instance
Privoxy
(N Privoxy instances)
Lan Web Applications
(Imule Web, susimail, i2psnark, I2P console, etc)
1 ... N
Dynamic random browser user agent
Tor Transport balanced instances by port range
(N RR balanced parent cache peers)
INTRANET
(Anon GW administration, N ARM instances, NAS, DHCP, NTPD, etc.)
Reverse Proxy
by Virtual Hosting
1...N
Local DNS resolver
Squid Cache Peer Proxy
TOR
VPN 1...N
(& ANONET & trusted public addresses)
LAN
INPUT rules
TCP Port 80
TCP Port 443
Other TCP Services
UDP FORWARD Blocked
BYPASS rules
PREROUTING rules by MAC Address
DHCPD pushes search local domains
IPTABLES
Default GW
UDP Port 123
LAN NTP server
UDP Port 5
LAN DNS serve
CLOCK
Private, public and virtual name resolution
BIND9 Cache
.onion, .i2p, .exit and invalid name
IP mapping for deepweb routing (ex. 10.192/10 and 67.215.65.132)
N TOR DNS services
+
DNS Crypt
FORWARDERS
Local Zones
OpenNIC doma (.glue, .oss, e
8 TOR instances per deep web surfer

Here the data flows of our anonymous surfer Jon Do...

Requirements:

1. A box with a dual core processor, two network interfaces and two hard drives.
2. Ubuntu server 12.04 64 bit.
3. RAID 1 (if paranoia/comfort > 1 then whole disk encrypted) and/or: random key encrypted swap, random key encrypted tmp logical volume and random key encrypted cache volume.
4. ISC DHCP, Bind9, DnsCrypt, NTPD, Squid3, N Privoxy instances, N TOR instances (where N is 8 * deep web surfer), I2P, Tahoe-LAFS-I2P, Freenet, Apache2, OpenVPN
5. Patience and passion

How it works:

1. Jon Do adds in the AnonGW the MAC address of his new laptop (or tablet or smartphone or anything else with the capability of web browsing and a known physical address...)
2. The laptop broadcasts its presence in the LAN, asking networking settings ==> the DHCP server (isc-dhcp) instructs which IP address, default gateway, NTP server, DNS server and which DNS domain to search are needed. The domain will be the local LAN domain and the VPN's domains (office, datacentre, etc.).
3. he laptop starts to synchronize its clock with the clock of the AnonGW. Jon Do searches "http://www.debian.org" in his browser and its DNS client queries AnonGW DNS server to resolve it. If the answer is not cached, the DNS server (bind9) forwards the query via TOR network or, as last attempt, via DnsCrypt on OpenDNS
4. HTTP request is intercepted by the cache proxy (Squid3) and "round robin" balanced over the N (ex. 8) Privoxy parent peers. The browser user agent are dinamically modified by a script (uagent.py) and forwarded via N (ex: 8) TOR instances.
5. Jon Do searches https://www.eff.org and open a ssh session on a public server: both connections are "transported" by two different instances of TOR.
6. Jon Do opens a new tab in his web browser and searches his Tor Mail "http://jhiwjjlqpyawmpjx.onion": the DNS server forwards directly to the TOR DNS service that resolves the ".onion" domain with a private address (ex: 10.192.0.1). HTTP request is intercepted by Squid and forwarded to Privoxy: it recognizes the "dot onion" domain and forwards it in the TOR network to find the "hidden service".
7. Jon Do opens again a new tab and searches "http://killyourtv.i2p.xyz/debian/": the DNS server forwards directly to the TOR DNS service that resolves the ".i2p.xyz" domain with a private address (ex: 10.192.0.2). HTTP request is always intercepted by Squid and forwarded to Privoxy: it recognizes the "dot i2p" domain and forwards it in the I2P network to find the "eepsite".
8. Entering only "i2p" in his address bar he has access to the i2p console or to a invisible torrent client on "https://i2p/i2psnark/": the DNS find in its local zones and resolves it with the AnonGW IP and the HTTP/HTTPS request is authenticated by the Apache2 I2P.JonDolocaldomain virtual host and forwarded via its reverse proxy to the i2p router.

9. Entering only "tahoe" in his address bar he has access to the Tahoe-LAFS welcome page: Jon Do can find the KYTV's Tahoe-LAFS debian repository on:

```
https://tahoe/uri/URI:DIR2-RO:mvp3so6kemo6fn6abddzjthnuu:jjg475us6hbmya3ccy
```

1. Entering only "freenet" in his address bar he has access to the Freenet console and can read the Toad's Flog on:

```
https://freenet/freenet:USK@yGvITGZzrY1vUZK-4AaYLgcjZ7ysRqNTMfdcO8gS-LY,-al
```

1. Jon Do can access to the LAN of his office via VPN: he has configured the DNS zone and the VPN service on his Anonymous Gateway. Anonet is the same concept: he has configured a VPN but the DNS forwards the ".ano" queries to the Anonet DNS.

2. Jon Do needs to do a different research and removes his MAC address from the "Deep Web Proxy rules" from the AnonGW and search "http://grep.geek": the DNS server forwards the queries to the OpenNIC DNS servers. He can surf free TLDs and normal clearnet without anonymization.

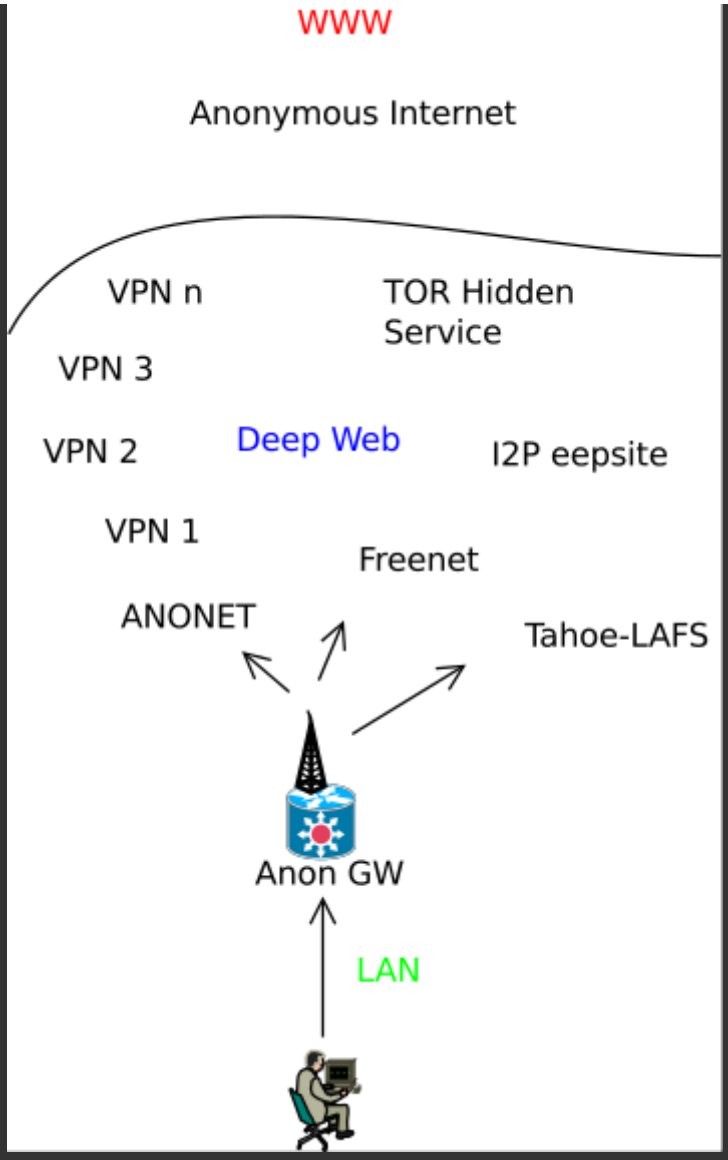
proof of concept

This is the idea...



One or more persons can gain internet resources in the most secure, fast and handy method via a server gateway that, via a proxy system, can route transparently all the traffic from layer 2 to layer 7 to reach local and remote services, in the clearnet or in the opennet/darknet.

Of course the best method for web anonymization is the use, for example, of the TOR bundle or Tails; but I think this is an excellent compromise for daily web surfing in west democratic (ROTFL) countries compared to the top paranoia in the "they can kill me" dictatorships.

Of course a good method to use the AnonGW is surfing with the TOR browser in transparent mode. The users don't need to install anything on their workstations and they can free resources and decrease complexity in their boxes (no java running on their laptops 🙂)

The AnonGW provides:

- DHCP service ==> automatically dictates the network rules to use the deep web proxy.
- Time service (NTP server) ==> syncronizes LAN clocks, no UDP leaks out of the LAN.
- DNS service (bind9) ==> (I) manages local zones for LAN services, VPN networks and reverse proxy (II) forwards the queries to the TOR network and, for a full answer, to OpenDNS via DNSCrypt.

- filtering service (iptables) ==> activate/deactivate the deep web proxy filtering mac address (layer 2 oriented).
- firewalling all protocols except toward VPN's and Anonet (layer 3 oriented).
- routing tcp via proxies (layer 4 oriented).
- web traffic managed through HTTP headers via direct cache, reverse and filtering web proxies (layer 7 oriented).
- access anonymously to web (clearnet and hidden services) through TOR: (I) fast HTTP via a round robin clustered cache proxy (Squid3) over multiple privoxy and TOR instances (II) HTTPS and other TCP services directly via TOR (transport mode).
- access to I2P resources: (I) eeepsites via Squid and Privoxy (II) I2P web clients via reverse proxy (Apache2 virtual host).
- access to Freenet resources: via reverse proxy (virtual host).
- access to Tahoe-LAFS storage grids in I2P (or TOR or anything else): via reverse proxy (virtual host) or via SSHFS.
- access to OpenNIC domains but note: only few exit nodes resolve these domains.

abstract

The objective of this blog is to be a tutorial to realize a high speed gateway to anonymize the Internet traffic and routing it to the main free spaces in the Internet.

The idea has born from the need to force myself to improve my privacy in my daily web surfing without renouncing too much to the performance and to have always available, with any workstation, the most important anonymous networks and services.

The Anonymous Gateway is a set of open source software customized to work together on a standard *nix platform.

Every post will be a "how to" configure every client and every server to reach the goal: a centralized set of tools for anonymization.

Every services is a world of knowledge and I will be glad if anyone will want to contribute to improve performance, security or anything else.

It would be nice developing a "simple web admin interface"; now I'm using a simple aggregation of links to the specific consoles or to the virtual hosts: I'm a sysadmin not a developer.

I hope this blog will also be useful to everyone looking for tutorials with working configurations of the most used open source software in server systems.

I used an Ubuntu Gnu/Linux server 12.04 (LTS) with apparmor enabled and with all its standard repository packages, included I2P repository for "Precise" mantained by KillYourTV (thank you!).
